**Trees**

Week 12

Gaddis: 20
Weiss: 21.1-3

CS 5301
Spring 2014

Jill Seaman

---

**Tree:**

non-recursive definition

- **Tree:** set of nodes and *directed* edges
  - **root:** one node is distinguished as the root
  - Every node (except root) has exactly exactly one edge coming into it.
  - Every node can have any number of edges going out of it (zero or more).
- **Parent:** source node of directed edge
- **Child:** terminal node of directed edge

---

**Tree:**

example

- edges are directed down (source is higher)
- D is the parent of H. Q is a child of J.
- **Leaf:** a node with no children (like H and P)
- **Sibling:** nodes with same parent (like K,L,M)

---

**Tree:**

recursive definition

- **Tree:**
  - is empty or
  - consists of a root node and zero or more nonempty subtrees, with an edge from the root to each subtree (a subtree is a Tree).

---

**Tree:**

Figure 4.1 Generic tree
Tree terms

- **Path**: sequence of (directed) edges
- **Length of path**: number of edges on the path
- **Depth of a node**: length of path from root to that node.
- **Height of a node**: length of longest path from node to a leaf.

Tree traversal

- **Tree traversal**: operation that converts the values in a tree into a list
  - Often the list is output
- **Pre-order traversal**
  - Print the data from the root node
  - Do a pre-order traversal on first subtree
  - Do a pre-order traversal on second subtree
  - Do a preorder traversal on last subtree

  This is recursive. What’s the base case?

Preorder traversal: Expression Tree

- print node value, process left tree, then right

  + + a * b c * d e f g

- prefix notation (for arithmetic expressions)

Postorder traversal: Expression Tree

- process left tree, then right, then node

  a b c + d e f + g * +

- postfix notation (for arithmetic expressions)
Inorder traversal: Expression Tree

- IF each node has 0 to 2 children, you can do inorder traversal
- process left tree, print node value, then process right tree
  \[ a + b \times c + (d \times e + f) \times g \]

infix notation (for arithmetic expressions)

Binary Trees

- **Binary Tree**: a tree in which no node can have more than two children.
- height: shortest: \( \log_2(n) \) tallest: \( n \)

Binary Trees: implementation

- Structure with a data value, and a pointer to the left subtree and another to the right subtree.

```c
struct TreeNode {
    <type> data;       // the data
    TreeNode *left;    // left subtree
    TreeNode *right;   // right subtree
};
```

- Like a linked list, but two “next” pointers.
- This structure can be used to represent any binary tree.

Binary Search Trees

- A special kind of binary tree
- A data structure used for efficient searching, insertion, and deletion.
- **Binary Search Tree property:**
  For every node \( X \) in the tree:
  - All the values in the **left** subtree are **smaller** than the value at \( X \).
  - All the values in the **right** subtree are **larger** than the value at \( X \).
- Not all binary trees are binary search trees.
Binary Search Trees

A binary search tree
Not a binary search tree

An inorder traversal of a BST shows the values in sorted order

Inorder traversal: 2 3 4 6 7 9 13 15 17 18 20

Binary Search Trees: operations

- insert(x)
- remove(x) (or delete)
- isEmpty() (returns bool)

- find(x) (returns bool)
- findMin() (returns <type>)
- findMax() (returns <type>)

BST: find(x)

Recursive Algorithm:

- if we are searching for 15 we are done.
- If we are searching for a key < 15, then we should search in the left subtree.
- If we are searching for a key > 15, then we should search in the right subtree.
**BST: find(x)**

Example: search for 9
- compare 9 to 15, go left
- compare 9 to 6, go right
- compare 9 to 7 go right
- compare 9 to 13 go left
- compare 9 to 9: found

**BST: findMin()**

- Smallest element is found by always taking the left branch.
- Pseudocode
- Recursive
- Tree must not be empty

```cpp
<typename> findMin (TreeNode t) {
  assert (!isEmpty(t))
  if (isEmpty(left(t)))
    return value(t)
  return findMin (left(t))
}
```

**BST: insert(x)**

- Algorithm is similar to find(x)
- If x is found, do nothing (no duplicates in tree)
- If x is not found, add a new node with x in place of the last empty subtree that was searched.

Inserting 13:
BST: insert(x)

- Pseudocode
- Recursive

```cpp
bool insert(<type> x, TreeNode t) {
    if (isEmpty(t))
        make t’s parent point to new TreeNode(x)
    else if (x < value(t))
        insert (x, left(t))
    else if (x > value(t))
        insert (x, right(t))
    //else x == value(t), do nothing, no duplicates
}
```

Linked List example:

- Append x to the end of a singly linked list:
  - Pass the node pointer by reference
  - Recursive

```cpp
void List::append (double x) {
    append(x, head);
}
```

```cpp
void List::append (double x, Node *& p) {
    if (p == NULL) {
        p = new Node();
        p->data = x;
        p->next = NULL;
    } else
        append (x, p->next);
}
```

BST: remove(x)

- Algorithm is starts with finding(x)
- If x is not found, do nothing
- If x is not found, remove node carefully.
  - Must remain a binary search tree (smallers on left, biggers on right).

```cpp
Figure 4.24: Deletion of a node (4) with one child, before and after
```

- Case 1: Node is a leaf
  - Can be removed without violating BST property
- Case 2: Node has one child
  - Make parent pointer bypass the Node and point to child
**BST: remove(x)**

- **Case 3: Node has 2 children**
  - Replace it with the minimum value in the right subtree
  - Remove minimum in right:
    - will be a leaf (case 1), or have only a right subtree (case 2)
      -- cannot have left subtree, or it’s not the minimum

**Binary heap data structure**

- A binary heap is a special kind of binary tree
  - has a restricted structure (must be complete)
  - has an ordering property (parent value is smaller than child values)
  - NOT a Binary Search Tree!
- **Used in the following applications**
  - Priority queue implementation: supports enqueue and deleteMin operations in O(log N)
  - Heap sort: another O(N log N) sorting algorithm.

**Binary Heap: structure property**

- **Complete binary tree**: a tree that is completely filled
  - every level except the last is completely filled.
  - the bottom level is filled left to right (the leaves are as far left as possible).

**Complete Binary Trees**

- A complete binary tree can be easily stored in an array
  - place the root in position 1 (for convenience)
Complete Binary Trees

Properties

- In the array representation:
  - put root at location 1
  - use an int variable (size) to store number of nodes
  - for a node at position $i$:
    - left child at position $2i$ (if $2i \leq \text{size}$, else $i$ is leaf)
    - right child at position $2i+1$ (if $2i+1 \leq \text{size}$, else $i$ is leaf)
    - parent is in position $\lfloor i/2 \rfloor$ (or use integer division)

Binary Heap: ordering property

- In a heap, if X is a parent of Y, value(X) is less than or equal to value(Y).
  - the minimum value of the heap is always at the root.

Heap: insert(x)

- First: add a node to tree.
  - must be placed at next available location, size+1, in order to maintain a complete tree.
- Next: maintain the ordering property:
  - if x is greater than its parent: done
  - else swap with parent, repeat
- Called “percolate up” or “reheap up”
- preserves ordering property
**Heap: deleteMin()**

- Minimum is at the root, removing it leaves a hole.
  - The last element in the tree must be relocated.
- First: move last element up to the root
- Next: maintain the ordering property, start with root:
  - if both children are greater than the parent: done
  - otherwise, swap the smaller of the two children with the parent, repeat
- Called “percolate down” or “reheap down”
- preserves ordering property
- \(O(\log n)\)
