Week 6: Intro to Loops

Gaddis: 5.2-6

CS 1428
Fall 2014

Jill Seaman

Control Flow
(order of execution)

- So far, control flow in our programs has included:
  ‣ sequential processing (1st statement, then 2nd statement…)
  ‣ branching (conditionally skip some statements).

- Chapter 5 introduces loops, which allow us to conditionally repeat execution of some statements.
  ‣ while loop
  ‣ do-while loop
  ‣ for loop

5.2 The `while` loop

- As long as the relational expression is true, repeat the statement
`while` syntax and semantics

- The while statement is used to repeat statements:

```
while (expression)
    statement
```

- How it works:
  ‣ expression is evaluated:
  ‣ If it is true, then statement is executed, then it starts over (and expression is evaluated again).
  ‣ If (when) it is false, then statement is skipped (and the loop is done).

`while` example

- Example:

```
int number = 1;

while (number <= 3)
{
    cout << "Student" << number << endl;
    number = number + 1;
}

cout << "Done" << endl;
```

Hand trace!

- Output

```
Student1
Student2
Student3
Done
```

5.3 Using `while` for input validation

- Inspect user input values to make sure they are valid.
- If not valid, ask user to re-enter value:

```
int number;

cout << "Enter a number between 1 and 10: ";
cin >> number;

while (number < 1 || number > 10) {
    cout << "Please enter a number between 1 and 10: ";
    cin >> number;
}

// Do something with number here
```

This expression is true when number is OUT of range.

Explain the valid values in the prompt

Don't forget to input the next value

Input Validation

- Checking for valid characters:

```
char answer;

cout << "Enter the answer to question 1 (a,b,c or d): ";
cin >> answer;

while (answer != 'a' && answer != 'b' &&
       answer != 'c' && answer != 'd')
{
    cout << "Please enter a letter a, b, c or d: ";
    cin >> answer;
}

// Do something with answer here
```

5.4 Counters

- Counter: a variable that is incremented (or decremented) each time a loop repeats.
- Used to keep track of the number of iterations (how many times the loop has repeated).

- Must be initialized before entering loop!!!!

Counters

- Example (how many times do they enter an invalid number?):

```
int number;
int count = 0;

cout << "Enter a number between 1 and 10: ";
cin >> number;

while (number < 1 || number > 10) {
    count = count + 1;
    cout << "Please enter a number between 1 and 10: ";
    cin >> number;
}

cout << count << " invalid numbers entered " << endl;

// Do something with number here
```

9

Counters

- Example, using the counter to control how many times the loop iterates:

```
cout << "Number   Number Squared" << endl;
cout << "------   --------------" << endl;

int  num = 1;        // counter variable
while (num <= 8) {
    cout << num << "               " << (num * num) << endl;
    num = num + 1;   // increment the counter
}
```
- Output:

```
Number   Number Squared
------   --------------
1          1
2          4
3          9
4          16
5          25
6          36
7          49
8          64
```

10

5.5 The `do-while` loop

- Execute the statement(s), then repeat as long as the relational expression is true.

11

`do-while` syntax and semantics

- The `do-while` loop has the test expression at the end:

```
do
    statement
while (expression);
```

Don't forget the semicolon at the end

- How it works:
  ‣ `statement` is executed.
  ‣ `expression` is evaluated:
  ‣ If it is true, then it starts over (and `statement` is executed again).
  ‣ If (when) it is false, the loop is done.
- `statement` always executes at least once. 12

do-while example

- Example:

```
int number = 1;
do
{
    cout << "Student" << number << endl;
    number = number + 1;
} while (number <= 3);

cout << "Done" << endl;
```

- Output
```
Student1
Student2
Student3
Done
```

13

do-while with menu

```
char choice;

do {
    cout << "A: Make a reservation." << endl;
    cout << "B: View flight status." << endl;
    cout << "C: Check-in for a flight." << endl;
    cout << "D: Quit the program." << endl;
    cout << "Enter your choice: ";

    cin >> choice;

    switch (choice) {
        case 'A':  // code to make a reservation
                   break;
        case 'B':  // code to view flight status
                   break;
        case 'C':  // code to process check-in
                   break;
    }
} while(choice != 'D');
```
14

Different ways to control the loop

- Conditional loop: body executes as long as a certain condition is true
  ‣ input validation: loops as long as input is invalid
- Count-controlled loop: body executes a specific number of times using a counter
  ‣ actual count may be a literal, or stored in a variable.
- Count-controlled loop follows a pattern:
  ‣ initialize counter to zero (or other start value).
  ‣ test counter to make sure it is less than count.
 ‣ update counter during each iteration.

15

5.6 The for loop

- The for statement is used to easily implement a count-controlled loop.

```
for (expr1; expr2; expr3)
    statement
```

- How it works:
  ‣ expr1 is executed (initialization)
  ‣ expr2 is evaluated (test)
  ‣ If it is true, then statement is executed, then expr3 is executed (update), then start over.
  ‣ If (when) it is false, then statement is skipped (and the loop is done).

16

The `for` loop flow chart

```
for (expr1; expr2; expr3)
    statement
```
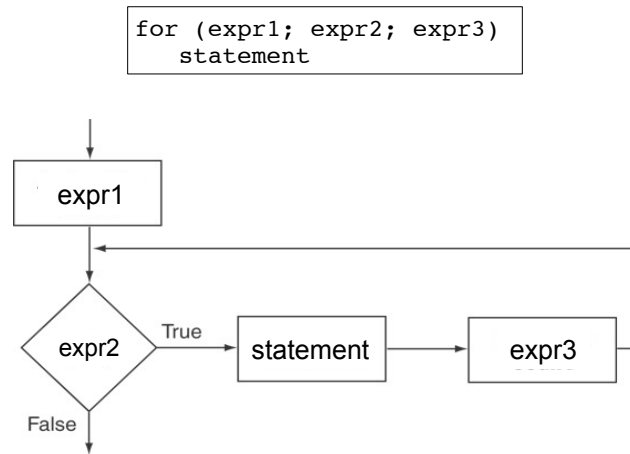

The `for` loop and the `while` loop

- The for statement

```
for (expr1; expr2; expr3)
    statement
```

- is equivalent to the following code using a while statement:

```
expr1;              // initialize
while (expr2) {     // test
    statement
    expr3;          // update
}
```

`for` loop example

- Example:

> Equivalent to
> number = number + 1

```
int number;
for (number = 1; number <= 3; number++)
{
    cout << "Student" << number << endl;
}

cout << "Done" << endl;
```

Note: no semicolon

- Output

```
Student1
Student2
Student3
Done
```

Counters: redo

- Example, using the counter to control how many times the loop iterates:

```
cout << "Number   Number Squared" << endl;
cout << "------   --------------" << endl;

int  num = 1;       // counter variable
while (num <= 8) {
    cout << num << "            " << (num * num) << endl;
    num = num + 1;  // increment the counter
}
```

- Rewritten using a for loop:

```
cout << "Number   Number Squared" << endl;
cout << "------   --------------" << endl;

int  num;
for (num = 1; num <= 8; num++)
    cout << num << "            " << (num * num) << endl;
```

Define variable in init-expr

- You may define the loop counter variable inside the for loop's initialization expression:

```
for (int x = 10; x > 0; x=x-2)        Hand trace!
   cout << x << endl;

cout << x << endl; //ERROR, can't use x here
```

- Do NOT try to access x outside the loop
  (the scope of x is the for loop statement ONLY)
- What is the output of the for loop?

21

User-controlled count

- You may use value input by the user to control the number of iterations:

```
int maxCount;
cout << "How many squares do you want?" << endl;
cin >> maxCount;

cout << "Number  Number Squared" << endl;
cout << "------  --------------" << endl;

for (int num = 1; num <= maxCount; num++)
   cout << num << "              " << (num * num) << endl;
```

- How many times does the loop iterate?

22

The exprs in the for are optional

- You may omit any of the three exprs in the for loop header

```
int value, incr;
cout << "Enter the starting value: ";
cin >> value;

for ( ; value <= 100; )
{
   cout << "Please enter the next increment amount: ";
   cin >> incr;
   value = value + incr;
   cout << value << endl;
}
```

- Style: use a while loop for something like this.
- When expr2 is missing, it is true by default.
