## Week 5: switch statements and programming with conditions

Gaddis: 4.10-15
CS 1428
Fall 2015
Jill Seaman

### 4.12 Comparing Characters and Strings

- Characters are compared using their ASCII values
${ }^{\prime} \mathrm{A}^{\prime}$ ' $^{\prime} \mathrm{B}^{\prime}{ }^{\prime}$
- This is true.

ASCII value of ' $A$ ' (65) is less than the ASCII value of ' $B$ '(66)
$\square$

- This is true

ASCII value of ' 1 ' (49) is less than the ASCI value of '2' (50)

- Lowercase letters have higher ASCII codes than uppercase letters, so 'a' > 'Z'

### 4.11 Validating User Input

- Input validation: inspecting input data to determine whether it is acceptable
- Invalid input is an error that should be treated as an exceptional case.
- The program can ask the user to re-enter the data
- The program can exit with an error message

```
cout << "Enter a positive number: ";
cin >> x;
    if (x > 0)
    //do something with x here
} else {
    cout << "You entered a negative number or 0." << endl;
    cout << "The program is ending." << endl;
}
```

## Comparing string objects

- Like characters, strings are compared using their ASCII values

```
string name1 = "Mary";
string name2 = "Mark";
name1 > name2 // true
name1 <= name2 // false
name1 != name2 // true
name1 < "Mary Jane" // true
```

The characters in each string must match exactly in order to be equal

Otherwise, use first nonequal character as basis of the comparison (' $y$ ' $>$ ' $k$ ')

If a string is a prefix of the other, then it is less than the other

### 4.14 The switch statement

- Like a nested if/else, used to select one of multiple alternative code sections.
- tests one integer/char expression against multiple constant integer/char values:

```
switch (expression) {
```

switch (expression) {
case const1: statements
case const1: statements
case const2: statements
case const2: statements
default: statements
default: statements
}

```
}
```

## switch statement behavior

```
switch (expression) {
    case const1: statements
    *
    case const2: statements
    default: statements
```

\}

- expression is evaluated to an int/char value
- execution starts at the case labeled with that int/char value
- execution starts at default if the int/char value matches none of the case labels

## switch statement example

- Example:

```
int quarter;
••
switch (quarter) {
    case 1: cout << "First";
        break;
    case 2: cout << "Second";
        break;
    case 3: cout << "Third";
    break;
    case 4: cout << "Fourth".
        break;
    default: cout << "Invalid choice";
}
```

## The break Statement

- The break statement causes an immediate exit from the switch statement.
- Without a break statement, execution continues on to the next set of statements (the next case).
- Sometimes this is useful: the textbook has some nice examples.

## Multiple labels

- if ch is 'a', it falls through to output "Option A" (then it breaks)

```
char ch;
...
switch (ch) {
    case 'a':
    case 'A': cout << "Option A";
    case 'b':
    case 'B': cout << "Option B";
    case B': break;
    case 'c':
    case 'C': cout << "Option C";
    default: cout << "Invalid choice";
}
```

## Sample menu code

```
// Display the menu and get a choice.
cout << "Health Club Membership Menu\n\n";
cout << "Health Club Membership Menu\n\n";
cout << "2. Child Membership\n";
cout << "3. Senior Citizen Membership\n";
    cout << "Enter your choice: ";
cin >> choice;
    // Respond to the user's menu selection.
switch (choice) {
    case 1:
        charges = months * 40.0;
        cout << "The total charges are $" << charges << endl;
        break
    charges = months * 20.0;
        cout << "The total charges are $" << charges << endl;
        break;
    case 3:
        charges = months * 30.0;
        cout << "The total charges are $" << charges << endl;
        break;
        cout << "ERROR: The valid choices are 1 through 3." << endl;
```

### 4.15 More about blocks and scope

- The scope of a variable is the part of the program where the variable may be used.
- The scope of a variable is the innermost block in which it is defined, from the point of definition to the end of that block.
- Note: the body of the main function is just one big block.

## Variables with the same name

- In an inner block, a variable is allowed to have the same name as a variable in the outer block.
- When in the inner block, the outer variable is not available (it is hidden).
- Not good style: difficult to trace code and find bugs

## Scope of variables in blocks

```
int main()
{
    double income; //scope of income is red + blue
    cout << "What is your annual income? ";
    cin >> income;
    if (income >= 35000)
        int years; //scope of years is blue;
        cout << "How many years at current job? ";
        cin >> years;
        if (years > 5
            cout << "You qualify.\n";
        else
        cout << "You do not qualify.\n";
    }
    else
    cout << "You do not qualify.\n";
    cout << "Thanks for applying.\n";
    return 0;
}
```

## Variables with the same name

```
int main()
{
    int number;
    cout << "Enter a number greater than 0: ";
    cin >> number;
    if (number > 0)
        int number; // another variable named number
        cout << "Now enter another number ";
        cin >> number;
        cout << "The second number you entered was ";
        cout << number << endl;
    }
    cout << "Your first number was " << number << endl;
}
```

Enter a number greater than 0:88 Now enter another number 2
The second number you entered was 2 Your first number was 88
