Trees & Heaps

Week 12

Gaddis: 20 Weiss: 21.1-3

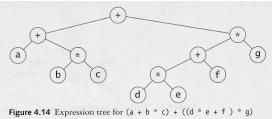

CS 5301 Spring 2017

Jill Seaman

Tree: non-recursive definition

- Tree: set of nodes and directed edges
 - root: one node is distinguished as the root
 - Every node (except root) has exactly exactly one edge coming into it.
 - Every node can have any number of edges going out of it (zero or more).
- Parent: source node of directed edge
- Child: terminal node of directed edge
- **Binary Tree**: a tree in which no node can have more than two children.

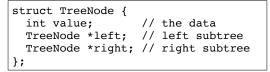

Tree Traversals: examples

- **Preorder:** print node value, process left tree, then right
- **Postorder:** process left tree, then right, then print node value a b c * + d e * f + g * +
- Inorder: process left tree, print node value, then process right tree a+b*c+d*e+f*g

Binary Trees: implementation

• Structure with a data value, and a pointer to the left subtree and another to the right subtree.

- Like a linked list, but two "next" pointers.
- There is also a special pointer to the root node of the tree (like head for a list).

4

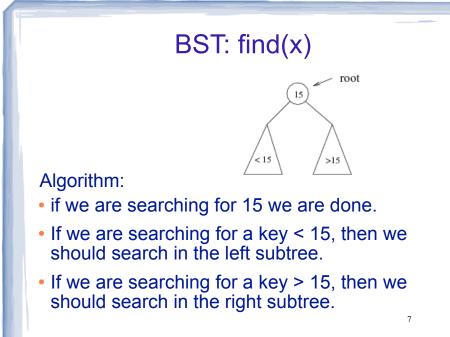

TreeNode *root;

Binary Search Trees

- A special kind of binary tree, used for efficient searching, insertion, and deletion.
- <u>Binary Search Tree property</u>: For every node X in the tree:
 - All the values in the **left** subtree are **smaller** than the value at X.
 - All the values in the **right** subtree are **larger** than the value at X.
- Not all binary trees are binary search trees
- An inorder traversal of a BST shows the values in sorted order

Binary Search Trees: operations

- insert(x)
- remove(x) (or delete)
- isEmpty() (returns bool)
 - if the root is NULL
- find(x) (or search, returns bool)
- findMin() (returns <type>)
 - Smallest element is found by always taking the left branch.
- findMax() (returns <type>)
 - Largest element is found by always taking the right branch.

BST: find(x)

• Defined iteratively:

bool IntBinaryTree::searchNode(int nu	ım)
{ TreeNode *p = root;	
while (p)	
if (p->value == num)	
return true;	
else if (num < p->value)	
p = p - > left;	
else	
p = p - right;	
}	
return false;	
}	

· Can also be defined recursively

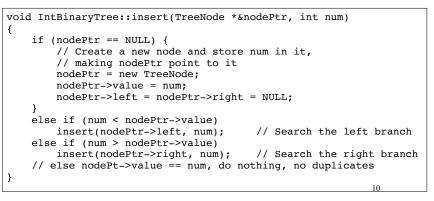

BST: insert(x)

- Algorithm is similar to find(x)
- If x is found, do nothing (no duplicates in tree)
- If x is not found, add a new node with x in place of the last empty subtree that was searched.

Inserting 13:

BST: insert(x)

- Recursive function
- root is passed by reference to this function

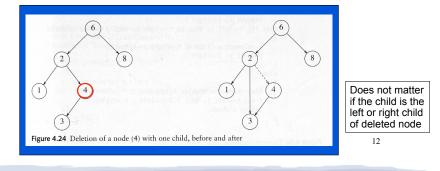

BST: remove(x)

- Algorithm is starts with finding(x)
- If x is not found, do nothing
- If x is found, remove node carefully.
 - Must remain a binary search tree (smallers on left, biggers on right).
 - The algorithm is described here in the lecture, the code is in the book (and on class website in **BinaryTree.zip**)

BST: remove(x)

- Case 1: Node is a leaf
 - Can be removed without violating BST property
- · Case 2: Node has one child
 - Make parent pointer bypass the Node and point to that child

Binary heap data structure

- A binary heap is a special kind of binary tree
 - has a restricted structure (must be complete)
 - has an ordering property (parent value is smaller than child values)
 - NOT a Binary Search Tree!
- Used in the following applications
 - Priority queue implementation: supports enqueue and deleteMin operations in O(log N)
 - Heap sort: another O(N log N) sorting algorithm.

Binary Heap: structure property

- Complete binary tree: a tree that is completely filled
 - every level except the last is completely filled.
 - the bottom level is filled left to right (the leaves are as far left as possible).

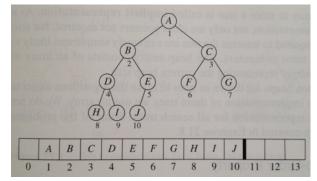

15

Complete Binary Trees

- A complete binary tree can be easily stored in an array
 - place the root in position 1 (for convenience)

16

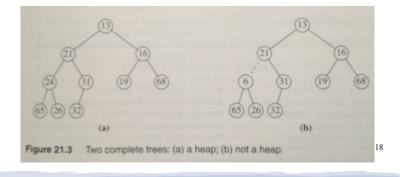

14

Complete Binary Trees Properties

- In the array representation:
 - put root at location 1
 - use an int variable (size) to store number of nodes
 - for a node at position i:
 - left child at position 2i (if 2i <= size, else i is leaf)
 - right child at position 2i+1 (if 2i+1 <= size, else i is leaf)
 - parent is in position floor(i/2) (or use integer division)
- There is a heap implementation on the class website in Heap.zip

Binary Heap: ordering property

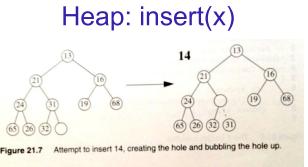

- In a heap, if X is a parent of Y, value(X) is less than or equal to value(Y).
- the minimum value of the heap is always at the root.

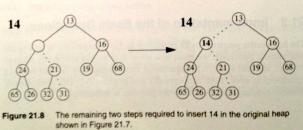

Heap: insert(x)

- First: add a node to tree.
 - must be placed at next available location, size+1, in order to maintain a complete tree.
- Next: maintain the ordering property:
 - if x doesn't have a parent: done
 - if x is greater than its parent: done
 - else swap with parent, repeat
- · Called "percolate up" or "reheap up"
- preserves ordering property

19

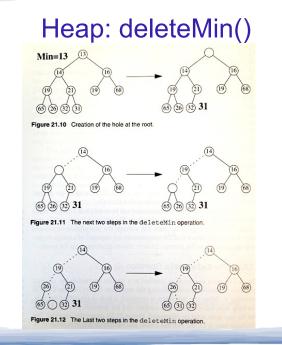

20

Heap: deleteMin()

- Minimum is at the root, removing it leaves a hole.
 - The last element in the tree must be relocated.
- First: move last element up to the root
- Next: maintain the ordering property, start with root:
 - if no children, do nothing.
 - if one child, swap with parent if it's smaller than the parent.
 - if both children are greater than the parent: done
 - otherwise, swap the smaller of the two children with the parent, and repeat on that child.
- Called "percolate down" or "reheap down"
- preserves ordering property
