

Block or compound statement

• a set of statements inside braces:

 This allows us to use multiple statements when by rule only one is allowed.

4

Input Validation

- Input validation: inspecting input data to determine whether it is acceptable
- Invalid input is an error that should be treated as an exceptional case.
 - The program can ask the user to re-enter the data

10

- The program can exit with an error message

cout << "Enter a score between 0 and 100: "; cin >> score; if (score < 0 || score > 100) { cout << "That is an invalid score." << endl; } else { //do something with score here }

More assignment statements

Compound assignment

operator	usage	equivalent syntax:
+=	x += e;	x = x + e;
_=	x -= e;	x = x - e;
*=	x *= e;	x = x * e;
/=	x /= e;	x = x / e;

• increment, decrement

operator	usage		equivalent syntax:	
++	x++;	++x;	x = x + 1;	
	x;	x;	x = x - 1;	

11

two kinds of loops conditional loop execute as long as a certain condition is true count-controlled loop: executes a specific number of times

- initialize counter to zero (or other start value).
- test counter to make sure it is less than count.
- update counter during each iteration.

cout << "Done" << endl;</pre>

do-while loops

• do while:

do
 statement
while (expression);

statement may be a compound statement (a block: {statements})

statement is executed. if expression is true, then repeat

• The test is at the end, statement ALWAYS executes at least once.

```
int number;
do {
   cout << "Enter a number, 0 when finished: ";
   cin << number;
   cout << "You entered " << number << endl;
} while (number != 0);
```

Keeping a running total (summing)

• Example:

```
int days;
float total = 0.0; //Accumulator
cout << "How many days did you ride your bike? ";
cin >> days;
for (int i = 1; i <= days; i++)
{
  float miles;
  cout << "Enter the miles for day " << i << ": ";
  cin >> miles;
  total = total + miles;
}
cout << "Total miles ridden: " << total << endl;</pre>
```

15

Sentinel controlled loop

 A sentinel controlled loop continues to process data until reaching a special value (called the sentinel) that signals the end.

get the first data item
while item is not the sentinel
 process the item
 get the next data item

 The first item is retrieved before the loop starts. This is called the priming read, since it gets the process started.

17

19

• If the first item is the sentinel, the loop terminates and no data is processed.

Sentinel controlled loop

• Example: summing using a sentinel

18

Nested loops

- When one loop appears in the body of another
- For every iteration of the outer loop, we do all the iterations of the inner loop

Output:	1	2	3	
	2	4	6	
	3	6	9	

continue and break Statements

- Use break to terminate execution of a loop
- When used in a nested loop, terminates the inner loop only.
- Use continue to go to end of **current** loop and prepare for next repetition
- while, do-while loops: go immediately to the test, repeat loop if test passes
- for loop: immediately perform update step, then test, then repeat loop if test passes

Example problem: Future Value

- Money deposited in a bank account earns interest annually. How much will the account be worth 10 years from now?
- Inputs: the principal and the annual interest rate
- Output: value of the investment in 10 years
- Relationship between Inputs and Outputs:

Value after one year is given by this formula: principal * (1 + apr) This needs to be done 10 times.

21

Example problem: Future Value

Design:

Print an introduction
Input the amount of the principal (principal)
Input the annual percentage rate (apr)
Repeat 10 times:
 principal = principal * (1 + apr)
Output the value of principal

22

Example problem: Future Value

Code:

int main() {
 cout << fixed << setprecision(2);
 double principal, apr;</pre>

//Print an introduction
cout <<"This program calculates the future ";
cout <<"value of a 10-year investment." << endl;</pre>

//Input the amount of the principal and interest cout << "Enter the initial principal: "; cin >> principal; cout << "Enter the annual interest rate: "; cin >> apr;

```
//Repeat 10 times:
for (int i=1; i<=10; i++)
    principal = principal * (1 + apr);
```

//Output the value of principal
cout << "The value in 10 years is: " << principal << endl; 23</pre>
