**Week 4**  
**Pointers & Structs**  
Gaddis: Chapters 9, 11

CS 5301  
Spring 2018  
Jill Seaman

---

**Pointers and Addresses**

- The **address operator** (&) returns the address of a variable.
  
  ```cpp
  int x;  
cout << &x << endl;  // 0xbffffb0c
  ```

- **Pointer**: a variable that stores the address of another variable, providing indirect access to it.
  
  ```cpp
  int *ptr;
  ptr = &x;
  ```

---

**Dereferencing and initializing**

- The unary operator * is the **dereferencing operator**.
- *ptr* is an alias for the variable that ptr points to.

  ```cpp
  int x = 10;  
  int *ptr;  //declaration, NOT dereferencing  
  ptr = &x;  //ptr gets the address of x  
  *ptr = 7;  //the thing ptr pts to gets 7
  ```

- **Initialization**:

  ```cpp
  int x = 10;  
  int *ptr = &x;  //declaration, NOT dereferencing
  ```

- ptr is a pointer to an int, and it is initialized to the address of x.

---

**Pointers as Function Parameters**

- Use pointers to implement pass by reference.

  ```cpp
  //prototype: void changeVal(int *);
  void changeVal (int *val) {
    *val = *val * 11;
  }
  ```

  ```cpp
  int main() {
    int x;
    cout << "Enter an int " << endl;
    cin >> x;
    changeVal(&x);
    cout << &x << endl;
  }
  ```

- **How is it different from using reference parameters?**
Pointers and Arrays

- You can treat an array variable as if it were a pointer to its first element.

```cpp
int numbers[] = {10, 20, 30, 40, 50};
```

Output:
```
first: 10
```

```cpp
cout << "first: " << numbers[0] << endl;
cout << "first: " << *numbers << endl;
cout << &(numbers[0]) << endl;
cout << numbers << endl;
```

```
Output:
first: 10
first: 10
0xbffffb00
0xbffffb00
```

- Pointer Arithmetic

- When you **add a value to a pointer**, you are actually adding n times the size of the data type being referenced by the pointer.

```cpp
int numbers[] = {10, 20, 30, 40, 50};
```

// Let us assume numbers is stored at 0xbffffb00
// Then numbers+1 is really 0xbffffb00 + 1*4, or 0xbffffb04
// And numbers+2 is really 0xbffffb00 + 2*4, or 0xbffffb08
// And numbers+3 is really 0xbffffb00 + 3*4, or 0xbffffb0c

```cpp
cout << "second: " << numbers[1] << endl;
cout << "second: " << *(numbers+1) << endl;
cout << "size: " << sizeof(int) << endl;
cout << numbers << endl;
cout << numbers+1 << endl;
```

```
Output:
second: 20
second: 20
0xbffffb00
0xbffffb04
```

- Note: array[index] is equivalent to *(array + index)

Pointers and Arrays

- **pointer operations** * + can be used with array variables.

```cpp
int list[10];
cin >> *(list+3);
```

- **subscript operations**: [ ] can be used with pointers.

```cpp
int list{} = {1,2,3};
int *ptr = list;
cout << ptr[2];
```

Comparing Pointers

- **pointers** (addresses) maybe compared using the relational operators:

  ```cpp
  < <= > => == !=
  ```

- **Examples**:

  ```cpp
  int arr[25];
  cout << (&arr[1] > &arr[0]) << endl;
cout << (arr == &arr[0]) << endl;
cout << (arr <= &arr[20]) << endl;
cout << (arr > arr+5) << endl;
  ```

- **What is the difference?**
  - `ptr1 < ptr2`
  - `*ptr1 < *ptr2`
Dynamic Memory Allocation

- When a function is called, memory for local variables is automatically allocated.
- When a function exits, memory for local variables automatically disappears.
- Must know ahead of time the maximum number of variables you may need.
- Dynamic Memory allocation allows your program to create variables on demand, during run-time.

The new operator

- “new” operator requests dynamically allocated memory for a certain data type:

  ```
  int *iptr;
  iptr = new int;
  ```
  
- new operator returns address of newly created anonymous variable.
- use dereferencing operator to access it:

  ```
  *iptr = 11;
  cin >> *iptr;
  int value = *iptr / 3;
  ```

Dynamically allocated arrays

- dynamically allocate arrays with new:

  ```
  int *iptr;  //for dynamically allocated array
  int size;
  cout << "Enter number of ints: ";
  cin >> size;
  iptr = new int[size];
  for (int i=1; i<size; i++) {
    iptr[i] = i;
  }
  ```
  
- Program will throw an exception and terminate if not enough memory available to allocate

delete!

- When you are finished using a variable created with new, use the delete operator to destroy it:

  ```
  int *ptr;
  double *array;
  ptr = new int;
  array = new double[25];
  . . .
  delete ptr;
  delete [] array;  // note [] required for dynamic arrays!
  ```
  
- Do not “delete” pointers whose values were NOT dynamically allocated using new!
- Do not forget to delete dynamically allocated variables (Memory Leaks!!).
Returning Pointers from Functions

- functions may return pointers:
  ```c
  int *findZero (int arr[]) {
    int *ptr;
    ptr = arr;
    while (*ptr != 0)
      ptr++;
    return ptr;
  }
  ```

- The returned pointer must point to:
  - dynamically allocated memory OR
  - an item passed in via an argument

  **NOTE:** if the function returns dynamically allocated memory, then it is the responsibility of the calling function to delete it.

Returning Pointers from Functions: duplicateArray

```c
int *duplicateArray (int arr[], int size) {
  int *newArray;
  if (size <= 0) //size must be positive
    return NULL; //NULL is 0, an invalid address
  newArray = new int [size]; //allocate new array
  for (int index = 0; index < size; index++)
    newArray[index] = arr[index]; //copy to new array
  return newArray;
}
```

Structures

- A structure stores a collection of objects of **various** types
- Each element in the structure is a member, and is accessed using the dot member operator.

```c
struct Student {
  int idNumber;
  string name;
  int age;
  string major;
};
```

- Defines a new data type
- Defines new variables

```c
Student student1, student2;
student1.name = "John Smith";
Student student3 = {123456,"Ann Page",22,"Math"};
```

Structures: operations

- **Valid operations over entire structs:**
  - assignment: student1 = student2;
  - function call: myFunc(gradStudent,x);

- **Invalid operations over structs:**
  - comparison: student1 == student2
  - output: cout << student1;
  - input: cin >> student2;
  - Must do these member by member
Arrays of Structures

- You can store values of structure types in arrays.
  
  Student roster[40]; //holds 40 Student structs

- Each student is accessible via the subscript notation.
  
  roster[0] = student1; //copy student1 into 1st position

- Members of structure accessible via dot notation
  
  cout << roster[0].name << endl;

Arrays of Structures: initialization

- To initialize an array of structs:
  
  ```
  struct Student {
    int idNumber;
    string name;
    int age;
    string major;
  };

  int main() {
    Student roster[] = {
      {111222,"Jack Spade",18,"Physics"}
    };
  }
  ```

Arrays of Structures

- Arrays of structures processed in loops:
  
  Student roster[40];

  //input
  for (int i=0; i<40; i++) {
    cout << "Enter the name, age, idNumber and "
    << "major of the next student: 
";
    cin >> roster[i].name >> roster[i].age
    >> roster[i].idNumber >> roster[i].major;
  }

  //output all the id numbers and names
  for (int i=0; i<40; i++) {
    cout << roster[i].idNumber << endl;
    cout << roster[i].name << endl;
  }

Passing structures to functions

- Structure variables may be passed as arguments to functions:
  
  ```
  void getStudent(Student &s) { // pass by reference
    cout << "Enter the name, age, idNumber and "
    << "major of the student: 
";
    cin >> s.name >> s.age >> s.idNumber >> s.major;
  }
  
  void showStudent(Student x) {
    cout << x.idNumber << endl;
    cout << x.name << endl;
    cout << x.age << endl;
    cout << x.major << endl;
  }
  ```

  // in main:
  Student student1;
  getStudent(student1);
  showStudent(student1);
We can define pointers to structures

```
Student s1 = {12345, “Jane Doe”, 18, “Math”};
Student *ptr = &s1;
```

To access the members via the pointer:

```
cout << *ptr.name << end; // ERROR: *(ptr.name)
```

dot operator has higher precedence, so use ():

```
cout << (**ptr).name << end;
```

or equivalently, use ->:

```
cout << ptr->name << end;
```

Dynamically Allocating Structures

Structures can be dynamically allocated with new:

```
Student *sptr;
sptr = new Student;
sptr->name = “Jane Doe”;
sptr->idNum = 12345;
...
delete sptr;
```

Arrays of structures can also be dynamically allocated:

```
Student *sptr;
sptr = new Student[100];
sptr[0].name = “John Deer”;...
delete [] sptr;
```

No arrows (->) necessary. It’s just an array of Student.
